SUMMARY. Aim. The main aim of the present study was to investigate the prevalence of Food Addiction (FA) and clinical level of Binge Eating in an Italian sample of overweight/obese patients attending low energy-diet therapy, and in an Italian sample of obese bariatric surgery candidates. Methods. Participants were: i) 122 overweight/obese patients (86 women) referred to a medical center in Rome (Italy), specialized in nutritional treatment of obesity (i.e., non-surgery patients group), and ii) 281 surgery candidates (207 women) referred to the center for Bariatric Surgery at the University of Rome Tor Vergata (i.e., surgery candidates group). All patients were administered self-report measures investigating FA, binge eating, and psychopathology. Results. Non-surgery patients and surgery candidates did not differ in the prevalence of FA (31.1% vs 26.3%), moderate level of binge eating (32.0% vs 31.8%), and severe level of binge eating (11.05% vs 13.6%). Compared to non-surgery patients, surgery candidates reported higher prevalence in two FA symptoms: i) food consumed more than planned (13.9% vs 25.3%; p=0.011) and ii) persistent desire or repeated unsuccessful attempts (89.3% vs 96.8; p=0.002). Discussion and Conclusion. Our results confirm that both FA and clinical level of binge eating are common problems in both overweight/obese patients seeking low-energy-diet therapy and in obese bariatric surgery candidates, justifying the clinical utility of assessing these dysfunctional eating patterns.

KEY WORDS: bariatric surgery candidates, binge eating, food addiction, obesity, overweight.

RIASSUNTO. Obiettivo. L’obiettivo principale del presente studio è stato quello di indagare la prevalenza della food addiction (FA) e di un livello clinicamente significativo di binge eating in: i) un campione italiano di pazienti obesi/sovrapeso in attesa di ricevere una dietoterapia, e ii) in un campione italiano di obesi candidati alla chirurgia bariatrica. Metodi. I partecipanti sono stati: i) 122 pazienti in sovrappeso/obesi (86 donne) che si sono rivolti a un centro medico privato di Roma, specializzato nel trattamento nutrizionale dell’obesità (gruppo non bariatrico), e ii) 281 candidati (207 donne) per la chirurgia bariatrica afferenti al centro per la Chirurgia Bariatrica dell’Università di Roma Tor Vergata (gruppo di candidati bariatrici). A tutti i pazienti sono stati somministrati dei questionari finalizzati alla valutazione della FA del binge eating e della psicopatologia. Risultati. I due gruppi non differivano nella prevalenza della FA (31,1% vs 26,3%), nella prevalenza del binge eating moderato (32% vs 31,8%), e nella prevalenza del binge eating severo (11,05% vs 13,6%). Rispetto al gruppo di pazienti non bariatrici, il gruppo di pazienti candidati alla chirurgia ha riportato un maggiore prevalenza in due sintomi della FA: consumo di cibo maggiore rispetto a quello pianificato (13,9% vs 25,3%; p=0,011), e ii) persistente desiderio e vani tentativi di smettere (89,3% vs 96,8; p=0,002). Discussione e conclusione. I nostri risultati confermano che sia la FA sia un livello clinico di binge eating sono problemi comuni sia nei pazienti sovrappeso/obesi che cercano una dietoterapia, sia nei pazienti che vorrebbero sottoporsi alla chirurgia bariatrica, giustificando l’assessment di questi pattern alimentari disfunzionali.

PAROLE CHIAVE: binge eating, chirurgia bariatrica, food addiction, obesity, sovrappeso.

INTRODUCTION

Obesity [i.e., body mass index (BMI) ≥30 kg/m²] and overweight (BMI ≥25 kg/m²) are often characterized by several dysfunctional eating patterns, especially binge eating1-3. A recent meta-analysis on 68 studies showed that, among patients seeking and undergoing bariatric surgery, Binge Eating Disorder (BED) is frequently diagnosed (about 17%)4. Similar-
ly, in large samples of non-bariatric obese seeking weight loss treatments, it has been reported, using self-report questionnaire, a prevalence of clinical level of binge eating of roughly 20%\textsuperscript{13,14}.

Binge eating is not the only dysfunctional eating pattern observed in both bariatric and non-bariatric obese. Among bariatric patients and overweight/obese adults seeking weight-loss treatments, Food Addiction (FA) appears to be a significant problem. Indeed, across published studies, the prevalence of FA ranges between 14% and 57% and between 15% and 25% respectively for bariatric patients\textsuperscript{5,12} and overweight/obese patients seeking weight-loss treatments\textsuperscript{13,17}.

To the best of our knowledge, no studies have investigated the prevalence of both FA and binge eating in these clinical samples. Therefore, the major aim of the present study was to extend these previous findings investigating the prevalence of these dysfunctional eating patterns in an Italian sample of overweight/obese patients seeking low-energy-diet therapy as well as in an Italian sample of obese bariatric surgery candidates. Investigating the prevalence of clinical level of binge eating and FA is compelling because it has been reported the association between these dysfunctional eating patterns and more negative treatment outcomes (e.g., poorer weight loss outcomes)\textsuperscript{2,19,18-20}.

**MATERIALS AND METHODS**

**Participants**

The study sample comprised: i) 122 overweight/obese patients (86 women and 36 men) referred to a medical center in Rome (Italy), specialized in nutritional treatment of obesity (i.e., non-surgery patients group), and ii) 281 surgery candidates (207 women and 74 men) referred to the center for Bariatric Surgery at the University of Rome Tor Vergata (i.e., surgery candidates group).

Non-surgery patients had an average BMI of 31.72 kg/m\textsuperscript{2} (SD=6.59; range: 25.04-53.40) and an average age of 41.92 years (SD=13.53; range: 18-73). In this group, there were 68 (55.7%) overweight and 54 (44.3%) obese patients. Surgery candidates had an average BMI of 44.01 kg/m\textsuperscript{2} (SD=7.82; range: 31.10-74.36) and an average age of 44.16 years (SD=11.17; range: 18-70). All patients were assessed at the time of study entry. Inclusion criteria were: age of 18 or higher; BMI of ≥25 kg/m\textsuperscript{2} for non-surgery patients; BMI of ≥30 for surgery candidates. Exclusion criteria were: history of neurologic diseases; purging and non-purging compensatory behaviours, the presence of any condition affecting the ability to complete the assessment, including the denial of informed consent. A checklist with dichotomous items was used to assess inclusion criteria and exclusion criteria. After receiving information about the aims of the study, all patients provided written consent to participate. The study was in accordance with the Helsinki declaration standards and was approved either by the ethics review board of the European University or by the Institutional Ethic Review Committee of the University of Rome Tor Vergata.

**Measures**

All of the participants were administered the Italian version of the Yale Food Addiction Scale (YFAS)\textsuperscript{23}, the Binge Eating Scale (BES)\textsuperscript{5}, and the Symptom Check List-90-R (SCL-90)\textsuperscript{22}. Sociode-
Prevalence of Food Addiction and Binge Eating in an Italian sample of bariatric surgery candidates

sample of overweight/obese patients seeking low-energy-diet therapy and in bariatric surgery candidates.

Our results are in line with previous studies investigating dysfunctional eating patterns in samples with similar socio-demographic variables<sup>5,12,16,23</sup>. In the present study the prevalence of FA clinical level of binge eating, and disordered eating symptoms did not differ between two groups. However, our results showed that surgery candidates reported diminished control over consumption of hyper-palatable food, as well as a more persistent desire or repeated unsuccessful attempts to quit. In bariatric surgery candidates, these features may explain the failure of diet therapy and it may negatively influence weight-loss after surgery<sup>29</sup>.

Our results are not in accordance with previous studies reporting a lower amount of problematic eating behaviors and psychopathology in patients seeking non-surgical weight loss treatment compared to bariatric patients<sup>30,31</sup>. The discrepancies between these results and the present research could be explained by several variables. First, our sample could be different in terms of socio-demographic (e.g., mean age) and clinical variable (e.g., mean BMI). The discrepancies may be also related by differences in study designs and methods (i.e., self-report vs structured interview). However, as already observed<sup>32</sup>, it is possible that patients who attended the psychosocial evaluation prior to surgery might minimize their psychological distress to obtain clearance for surgery. Finally, another possible explanation is in accordance with the hypothesis of a non-linear relationship between FA and BMI<sup>33</sup>, suggesting that FA might increase in the overweight and obese individuals, coming to rest at severe obesity level. Similarly, it has been hypothesized that the influence of BMI on binge eating had a ceiling effect meaning that when a level of BMI was reached the eating disorder could not worsen<sup>34</sup>.

Regardless of its limitations (e.g. the use of self-report, the use of the old version of YFAS), our results confirm that both binge eating and FA are common problems in overweight and obese seeking different weight-loss treatments, justifying the clinical utility of assessing these dysfunctional eating pattern through reliable, valid and multiple methods (i.e., self-reports and clinical interviews)<sup>33,34</sup>.
